

MEDICATION-INDUCED PSYCHOSIS

Monday, January 9, 2017

Many nonpsychiatric medications can cause psychiatric effects, which range from anxiety to psychosis. Drug-induced psychosis was first diagnosed in the 19th century. Since then, many medications have been associated with this phenomenon. The most commonly implicated medications include antiparkinsonian agents, cardiac medications and corticosteroids.

The term psychosis was first used in the 19th century to describe an abnormal state of mind.⁶ Today, psychosis represents a disturbance in the perception of reality. Psychosis is marked by the presence of one or more of the following symptoms: hallucinations, delusions, disorganized thoughts, and unusual, strange, and/or regressed behavior. - See more at:
